

Fractions, Decimals and Percentages — Mark schemes

PAPERS A TO D • 30 MARKS EACH • TUTOR COPY

Marks in square brackets show how the total is split. Where a question is worth more than one mark, award method marks even when the final answer is wrong — and take them away for a correct answer with no working only if the question said "show your working". The notes under each answer flag the specific mistake that question was built to catch.

Paper A — Medium

30 MARKS • NON-CALCULATOR

- 1 Row 1: 0.75 and 75%. Row 2: $\frac{7}{20}$ and 35%. Row 3: $\frac{3}{5}$ and 0.6. [6]
One mark per correct box. $\frac{35}{100}$ not simplified to $\frac{7}{20}$ loses that one box only.
- 2 (a) $\frac{45}{100} = \frac{9}{20}$ [2]
 (b) $\frac{24}{100} = \frac{6}{25}$
- 3 (a) $7 \div 8 = 0.875$ [2]
 (b) $5 \div 16 = 0.3125$
- 4 (a) $\frac{12}{20} + \frac{5}{20} = \frac{17}{20}$ [4]
 (b) $\frac{5}{6} - \frac{2}{6} = \frac{3}{6} = \frac{1}{2}$
 (c) $\frac{18}{30} = \frac{3}{5}$
 (d) $\frac{3}{4} \times \frac{5}{2} = \frac{15}{8} = 1 \frac{7}{8}$
Award the mark for a correct unsimplified answer only if the question did not ask for simplest form — here it did.
- 5 (a) 120 [3]
 (b) 9
 (c) 30
(c) is $\frac{1}{8}$ of 240. Halving three times is quicker than any other route.
- 6 Converting all four to decimals: 0.7, 0.6, 0.65, 0.667 [1]
 Order: $\frac{3}{5}$, 65%, $\frac{2}{3}$, 0.7 [1]
The second mark requires the original forms. Answering 0.6, 0.65, 0.667, 0.7 loses it.
- 7 1200×0.8 [1]
 = 960 rupees [1]
Finding 240 and stopping scores 1 — that is the discount, not the sale price.
- 8 40% of 30 = 12 wear glasses [1]
 30 – 12 = 18 [1]
Or 60% of 30 directly. Answering 12 scores 1: the question asked who does not.
- 9 (a) $500 \div 4 = 125$, so $3 \times 125 = 375$ g [2]
 (b) $500 - 375 = 125$ g [1]
- 10 (a) $\frac{18}{24} = \frac{3}{4}$ [2]
 (b) 75%
- 11 8000×1.05 [1]
 = 8400 rupees [1]

Paper B — Medium

30 MARKS • NON-CALCULATOR

- 1** (a) $13/5$ [2]
(b) $4 \frac{1}{4}$
- 2** (a) $3/2 + 11/4 = 6/4 + 11/4 = 17/4 = 4 \frac{1}{4}$ [4]
(b) $10/3 - 11/6 = 20/6 - 11/6 = 9/6 = 1 \frac{1}{2}$
(c) $5/4 \times 12/5 = 60/20 = 3$ [2]
In (c), one mark for converting both mixed numbers to improper fractions, one for the answer.
- 3** Decimals: 0.46, 0.444, 0.43, 0.45 [1] [2]
Order: 43%, $4/9$, $9/20$, 0.46 [1]
- 4** 250×1.12 [1] [2]
 $= 280$ [1]
- 5** 640×0.85 [1] [2]
 $= 544$ [1]
- 6** Change = $800 - 680 = 120$ [1] [3]
 $120 \div 800$ [1]
 $= 15\%$ decrease [1]
Dividing by 680 instead of 800 gives 17.6% — the single most common error in this topic. Award the first mark only.
- 7** Change = $4600 - 4000 = 600$ [1] [3]
 $600 \div 4000$ [1]
 $= 15\%$ increase [1]
- 8** $320 \div 8 = 40$, so 3×40 [1] [2]
 $= 120$ [1]
- 9** $5/8$ of 400 = 250 [1] [3]
60% of 420 = 252 [1]
60% of 420 is larger (by 2) [1]
The third mark is for the conclusion in words. Two correct numbers with no statement scores 2.
- 10** 68% of 250 = 170 full [1] [2]
250 – 170 = 80 empty [1]
Or 32% of 250 directly.
- 11** $375/1000 = 3/8$ [1] [2]
37.5% [1]
- 12** Boys = $40 - 24 = 16$ [1] [3]
 $16/40$ [1]
 $= 40\%$ [1]
Answering 60% means the student found the girls. That scores nothing beyond the method mark.

Paper C — Hard

30 MARKS • NON-CALCULATOR

- 1** (a) Terminates, 0.1875 ($16 = 2 \times 2 \times 2 \times 2$) [3]
(b) Recurs, 0.41666... (12 has a factor of 3)
(c) Terminates, 0.28 ($25 = 5 \times 5$)
Both halves needed for each mark. A fraction terminates only when the denominator, in simplest form, has no prime factors other than 2 and 5.

- 2** The multiplier for a 20% increase is 1.2 [1] [3]
 Original = $96 \div 1.2$ [1]
 = 80 rupees [1]
Taking 20% off 96 gives 76.80 and scores zero. You must divide, not subtract.
- 3** The multiplier for a 25% decrease is 0.75 [1] [3]
 Original = $180 \div 0.75$ [1]
 = 240 rupees [1]
- 4** (a) Starting from 100: $100 \times 1.1 = 110$, then $110 \times 0.9 = 99$, which is not 100 [2] [3]
 (b) $1.1 \times 0.9 = 0.99$, so an overall 1% decrease [1]
Any starting value is acceptable in (a). The second 10% is taken off a larger number than the first was added to, so the two never cancel.
- 5** $\frac{3}{5}$ of 450 = 270 [1] [3]
 $\frac{2}{3}$ of 270 [1]
 = 180 [1]
Also acceptable: $\frac{2}{3} \times \frac{3}{5} = \frac{2}{5}$, then $\frac{2}{5}$ of 450 = 180. Full marks for either route.
- 6** (a) Shop A: $2400 \times 0.7 = 1680$ [1] [4]
 Shop B: $2400 \times 0.75 = 1800$, then $1800 \times 0.9 = 1620$ [1]
 (b) Shop B is cheaper [1], by $1680 - 1620 = 60$ rupees [1]
Adding 25% and 10% to get 35% off is the trap. Successive percentage changes multiply.
- 7** $\frac{5}{8}$ of 640 = 400 [1] [3]
 15% of 400 [1]
 = 60 [1]
- 8** Losing 12% leaves 88%, so the multiplier is 0.88 [1] [3]
 $4.4 \div 0.88$ [1]
 = 5 kg [1]
Adding 12% to 4.4 gives 4.93 and scores at most the first mark.
- 9** Recognising a single recurring digit gives ninths [1] [2]
 = $\frac{4}{9}$ [1]
Worth memorising: $0.111... = \frac{1}{9}$, so $0.444... = \frac{4}{9}$ and $0.777... = \frac{7}{9}$.
- 10** Overall multiplier = $0.65 \times 0.9 = 0.585$ [1] [3]
 So the customer pays 58.5% of the original, a discount of 41.5% [1]
 The sign is wrong because the two discounts have been added; the second 10% is taken off an already reduced price, so it is worth less than 10% of the original [1]

Paper D — Hard

30 MARKS · NON-CALCULATOR

- 1** Profit = $600 - 480 = 120$ [1] [3]
 $120 \div 480$ [1]
 = 25% profit [1]
Percentage profit is always measured against the cost price, never the selling price.
- 2** A 20% loss means he received 80%, so the multiplier is 0.8 [1] [3]
 $640 \div 0.8$ [1]
 = 800 rupees [1]
- 3** (a) After books he has $\frac{2}{3}$ left. He then spends $\frac{1}{4}$ of that, so he keeps $\frac{3}{4}$ of $\frac{2}{3}$ [1] [4]
 $\frac{3}{4} \times \frac{2}{3} = \frac{1}{2}$ [1]
 (b) $\frac{1}{2}$ of the original = 900 [1], so he started with 1800 rupees [1]
The trap is adding $\frac{1}{3}$ and $\frac{1}{4}$ to get $\frac{7}{12}$ spent. The second fraction is of the remainder, not of the original.

- 4** Fraction removed = $\frac{3}{5} - \frac{1}{3}$ [1] [4]
 = $\frac{9}{15} - \frac{5}{15} = \frac{4}{15}$ [1]
 $\frac{4}{15}$ of the capacity = 240, so $\frac{1}{15} = 60$ [1]
 Capacity = $60 \times 15 = 900$ litres [1]
- 5** Deal 1: $600 \times 0.8 \times 0.9 = 432$ [2] [4]
 Deal 2: $600 \times 0.75 \times 0.95 = 427.50$ [1]
 Deal 2 is better, by 4.50 rupees [1]
Both deals total 30% if you add them, which is exactly why they look identical and are not.
- 6** Take the original as 100; after a 25% rise it is 125 [1] [4]
 The fall needed is 25 out of 125 [1]
 $25 \div 125 = 0.2$ [1]
 So the price must fall by 20% [1]
Answering 25% scores at most one mark. The fall is measured against the new, larger price — this is the same idea as the 10% up-and-down question on Paper C.
- 7** Girls = $\frac{3}{5}$ of 500 = 300, so boys = 200 [1] [4]
 25% of 300 = 75 girls walk [1]
 40% of 200 = 80 boys walk [1]
 Total = $75 + 80 = 155$ students [1]
Averaging 25% and 40% to get 32.5% of 500 gives 162.5 and scores nothing. The two groups are different sizes.
- 8** (i) The mistake: comparing decimals by the size of the digits after the point instead of by place value [1] [4]
 Padding with a zero gives 0.90 against 0.15, so 0.9 is larger [1]
 (ii) The mistake: adding the numerators and the denominators separately [1]
 Using a common denominator: $\frac{3}{6} + \frac{2}{6} = \frac{5}{6}$ [1]
A useful check for (ii): the answer must be bigger than $\frac{1}{2}$, and $\frac{2}{5}$ is smaller — so it is wrong before you calculate anything.
